

CONFIRMED
AUGUST 1990

Specification for

Fine pitch gears —

Part 1: Involute Spur and Helical Gears

UDC 621.833.1

Co-operating organizations

The Mechanical Engineering Industry Standards Committee, under whose supervision this British Standard was prepared, consists of representatives from the following Government departments and scientific and industrial organizations:

Associated Offices' Technical Committee	Institution of Civil Engineers
Association of Consulting Engineers*	Institution of Gas Engineers
Association of Mining Electrical and Mechanical Engineers*	Institution of Heating and Ventilating Engineers
Board of Trade	Institution of Mechanical Engineers
British Chemical Plant Manufacturers' Association	Institution of Mechanical Engineers (Automobile Division)
British Compressed Air Society	Institution of Production Engineers*
British Electrical and Allied Manufacturers' Association*	Locomotive and Allied Manufacturers' Association of Great Britain
British Gear Manufacturers' Association*	London Transport Board
British Internal Combustion Engine Manufacturers' Association	Machine Tool Trades Association*
British Iron and Steel Federation	Ministry of Defence
British Mechanical Engineering Federation	Ministry of Labour (H.M. Factory Inspectorate)
British Pump Manufacturers' Association	Ministry of Power
Crown Agents for Oversea Governments and Administrations	Ministry of Public Building and Works
Electricity Council, the Central Electricity Generating Board and the Area Boards in England and Wales	Ministry of Technology — National Engineering Laboratory*
Engineering Equipment Users' Association	Ministry of Transport
Gas Council	National Coal Board
Institute of Marine Engineers*	National Physical Laboratory (Ministry of Technology)
	Radio Industry Council
	Royal Institute of British Architects

The Government department and scientific and industrial organizations marked with an asterisk in the above list, together with the following, were directly represented on the committee entrusted with the preparation of this standard:

British Horological Institute	Ministry of Technology
Electronic Engineering Association	Navy and Vickers Gearing Research Association
Institute of British Foundrymen	North-East Coast Institution of Engineers and Shipbuilders
Institution of Engineering Inspection	Society of Motor Manufacturers and Traders Ltd.
Institution of Engineers and Shipbuilders in Scotland	University of Sheffield
Milling Cutter and Reamer Association	Manufacturers of fine pitch gears
Ministry of Defence, Army Department	
Ministry of Defence, Navy Department	

This British Standard, having been approved by the Mechanical Engineering Industry Standards Committee and endorsed by the Chairman of the Engineering Divisional Council, was published under the authority of the General Council on 31 January 1968

Foreword

This standard makes reference to the following British Standards:

BS 978, *Fine pitch gears*.

BS 978-2, *Cycloidal type gears*.

BS 978-PD 3376, *Addendum No. 1 to BS 978-2, Double circular arc type gears*.

BS 978-3, *Bevel gears*.

BS 978-5, *Hobs and cutters*.

First published in 1952 and revised in 1962, this British Standard has been further revised under the authority of the Mechanical Engineering Industry Standards Committee.

In the 1962 edition, dual flank composite testing was introduced in the form of an appendix to the specification. As this method of test became more widespread, users of the standard were becoming confused between the application of the composite tolerances and application of the individual elemental tolerances. The prime reason for revision, therefore, has been to give dual flank testing the importance it now deserves by placing it in the mandatory part of the standard as the main accuracy testing procedure. Also care has been taken to ensure that the user is not misled by attempting to reconcile composite errors with elemental errors. It is necessary to retain the elemental tolerances because these will continue to be used in some fields as acceptance criteria and because they are essential as the basis for manufacturing gears and cutting tools¹⁾. Recognizing also that single flank testing is used reference to this is made in an appendix.

Opportunity has been taken to effect improvements in presentation and in the examples of calculations, and the terminology and notation is in accordance with that agreed within the International Organization for Standardization (ISO).

This standard is a companion work to BS 978, "*Fine pitch gears*", Part 2, "*Cycloidal type gears*" (including addendum PD 3376, "*Double circular arc type gears*"), Part 3, "*Bevel gears*", and Part 5, "*Hobs and cutters*".

A British Standard does not purport to include all the necessary provisions of a contract. Users of British Standards are responsible for their correct application.

Compliance with a British Standard does not of itself confer immunity from legal obligations.

Summary of pages

This document comprises a front cover, an inside front cover, pages i to iv, pages 1 to 29 and a back cover.

This standard has been updated (see copyright date) and may have had amendments incorporated. This will be indicated in the amendment table on the inside front cover.

¹⁾ BS 978, "*Fine pitch gears*", Part 5, "*Hobs and cutters*".

1 General

1.1 Scope

This British Standard relates to involute spur, helical and crossed helical gears, having diametral pitches finer than 20, in four accuracy grades. Examples of application are:

Class A. Astronomical apparatus and scientific instruments; colour printing machinery; control systems (when multiple trains of gears are involved this grade would generally be used for low speed components where the effect of positional accuracy is important).

Class B. Navigational instruments; high speed components of control systems where quietness and smooth running are essential; machine tool speed control; photographic instruments.

Class C. General purpose instruments; accounting and calculating machinery; counters; clockwork mechanisms.

Class D. Textile machinery; switch operating gear; clockwork mechanisms where accuracy is not the primary consideration.

It is recommended that all spur, helical and crossed helical gears for use in horology should be produced to this British Standard with the possible exception of gears for weight or spring-driven mechanisms in which the pinion is the driven member and has 12 or fewer teeth. In such cases it may be preferable to use gears conforming to BS 978-2²⁾.

1.2 Terminology and notation

As the first step towards achieving international understanding of gears terminology, the terms and definitions of Draft ISO Recommendation No. 888³⁾, "International vocabulary of gears", have been applied, together with corresponding notation derived from Draft ISO Recommendation No. 889, "International gear notation, symbols for geometrical data"³⁾.

The notation used is as follows:

a	Centre distance
a_v	Virtual centre distance
d	Reference circle diameter
d_1	Reference circle diameter: pinion
d_2	Reference circle diameter: wheel
d_a	Tip diameter
d_{a1}	Tip diameter: pinion
d_{a2}	Tip diameter: wheel
d_R	Measuring pin diameter
d_b	Base circle diameter
j_n	Normal backlash
j^a	Coefficient for calculation of backlash
l	Length of arc
P_n	Normal diametral pitch
s	Arc tooth thickness
s_1	Arc tooth thickness: pinion
s_2	Arc tooth thickness: wheel
x	Addendum modification coefficient
x_1	Addendum modification coefficient: pinion
x_2	Addendum modification coefficient: wheel
Δx_1	Secondary addendum modification coefficient: pinion
Δx_2	Secondary addendum modification coefficient: wheel
y	Centre distance modification coefficient

²⁾ BS 978, "Fine pitch gears", Part 2, "Cycloidal type spur gears".

³⁾ To be incorporated in BS 2519, "Glossary of terms for toothed gearing".

- z Number of teeth
- z_1 Number of teeth: pinion
- z_2 Number of teeth: wheel
- z_v Virtual number of teeth
- α_n Normal pressure angle
- α_{nw} Normal pressure angle, operating
- α_t Transverse pressure angle
- α_{tw} Transverse pressure angle, operating
- β Helix angle at reference cylinder
- β_b Helix angle at base cylinder

^a BS 978, "Fine pitch gears", Part 5, "Hobs and cutters".

1.3 Preferred range of normal diametral pitches

The pitch shall be selected from the following preferred range.

**Table 1 — Normal diametral pitch P_n
(inch units)**

	32	48	100	160
24	36	64	120	180
28	40	80	140	200

1.4 Basic rack tooth profile

The shape and proportions of the basic rack tooth for spur helical and crossed helical gears shall be as shown either in Figure 1 or Figure 2. In the case of helical and crossed helical gears, the shape and proportions of the tooth are on a section at right angles to the pitch cylinder helix.

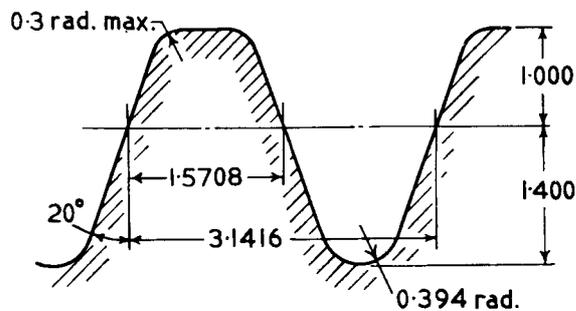

Figure 1 — Basic rack tooth profile for unit normal diametral pitch

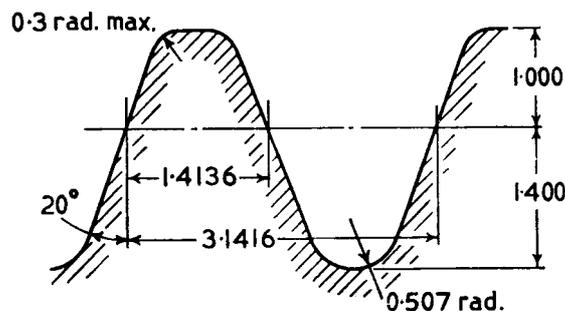

Figure 2 — Basic rack tooth profile for unit normal diametral pitch with backlash allowance

Figure 1 shows the basic rack usually employed where it is desired to have minimum backlash, as in servomechanisms.

Figure 2 is used where it is desired to have backlash to avoid any risk of jamming and where the load is usually uni-directional, for example, in clockwork mechanisms. When non-topping hobs are used it is permissible to use a hob conforming to Figure 1 basic rack and to cut at greater depth than normal to obtain the required tooth thickness.

For internal gears (Figure 1 and Figure 2 basic racks) the addendum shall normally be 0.850 instead of 1.000. In cases when the tips of the teeth have a radius of 0.25 or greater (up to 0.3 max. as shown) the 1.000 addendum may be applied.

2 Design details

2.1 Outside diameter and centre distance

For the normal case when both $z_1 \sec^3\beta$ and $z_2 \sec^3\beta$ are greater than 17 the dimensions are as follows:

$$d_1 = \frac{z_1 \sec\beta}{P_n} \quad (1) \quad d_2 = \frac{z_2 \sec\beta}{P_n} \quad (2)$$

$$d_{a1} = \frac{z_1 \sec\beta + 2}{P_n} \quad (3) \quad d_{a2} = \frac{z_2 \sec\beta + 2}{P_n} \quad (4)$$

$$a = \frac{(z_1 + z_2) \sec\beta}{2P_n} \quad (5)$$

(For spur gears, $\sec\beta = 1$)

2.2 Modification of addendum and centre distance

2.2.1 For an explanation of the principles followed in connection with addendum modification see Appendix A.

2.2.2 Where no limitations are imposed, the value of x for any gear whose virtual number of teeth z_v is less than 17 is given by the formulae:

$$x = 1 - \frac{z_v \sin^2 \alpha}{2} \quad (6) \quad \text{(See Table 2 and Figure 3 and Figure 4)}$$

$$\text{where } z_v = z \sec\beta \sec^2\beta_b \approx z \sec^3\beta \quad (7)$$

This gives values in accordance with the lower limiting line XX in Figure 3 and a small and normally negligible amount of undercutting is thereby permitted.

The addendum modification coefficient for helical pinions from 6 to 16 teeth and helix angles up to 45° is shown in Figure 4.

2.2.3 When the pinion is modified as above and there are no other limitations, the wheel is unmodified and its dimensions are obtained from the formulae in **2.1**; but the dimensions of the pinion and centre distance are as follows:

$$d_{a1} = \frac{z_1 \sec\beta + 2(1 + x_1)}{P_n} \quad (8)$$

$$s_1 = \frac{1.5708 + 0.7279x_1}{P_n} \quad \text{(Figure 1 type gears)} \quad (9)$$

$$s_1 = \frac{1.4136 + 0.7279x_1}{P_n} \quad \text{(Figure 2 type gears)} \quad (10)$$

$$a = \frac{(z_1 + z_2) \sec\beta + 2x_1}{2P_n} \quad (11)$$

Parallel axis external gear pairs designed as above have backlash at this centre distance. (See Appendix A.)

Table 2 — Data for spur pinions of unit diametral pitch having fewer than 17 teeth

No. of teeth z_1	Addendum modification coefficient x_1	Tip diameter d_{a1}	Increase in circular tooth thickness at standard pitch dia.	Recommended minimum number of teeth in mating wheel z_2
8 ^a	0.5321	11.0642	0.3874	26
9 ^a	0.4736	11.9472	0.3448	25
10	0.4151	12.8302	0.3022	24
11	0.3566	13.7132	0.2596	23
12	0.2982	14.5963	0.2170	22
13	0.2397	15.4793	0.1744	21
14	0.1812	16.3623	0.1319	20
15	0.1227	17.2453	0.0893	19
16	0.0642	18.1284	0.0467	18

^a Pinions having 8 or 9 teeth generated from basic rack Figure 1 have narrow crest width, as also have pinions of 10 and 11 teeth generated from basic rack Figure 2. 10 is the smallest number of teeth that can be generated at full depth from basic rack Figure 2.

2.2.4 Enlarged spur pinions with minimum backlash. Spur pinions enlarged according to Table 2 may be engaged with wheels in which x_2 is zero, at centre distance derived from Table 3. Gears derived from Figure 1 basic rack will have no backlash at this centre distance. A small and negligible reduction of tip-to-root clearance is obtained at this centre distance.

Table 2 is not applicable to helical gears, for which the formulae in Appendix A are required.

Alternatively, spur pinions enlarged according to Table 2 or helical pinions enlarged according to Figure 4 may be engaged with wheels in which $x_2 = -x_1$, in which case the centre distance is as obtained in 2.1, and

$$s_2 = \frac{1.5708 - 0.7279x_1}{P_n} \quad (\text{Figure 1 type gears}) \quad (12)$$

$$s_2 = \frac{1.4136 - 0.7279x_1}{P_n} \quad (\text{Figure 2 type gears}) \quad (13)$$

$$d_{a2} = \frac{z_2 \sec\beta + 2(1 - x_1)}{P_n} \quad (14)$$

Such gears derived from Figure 1 basic rack will have zero backlash at nominal dimensions.

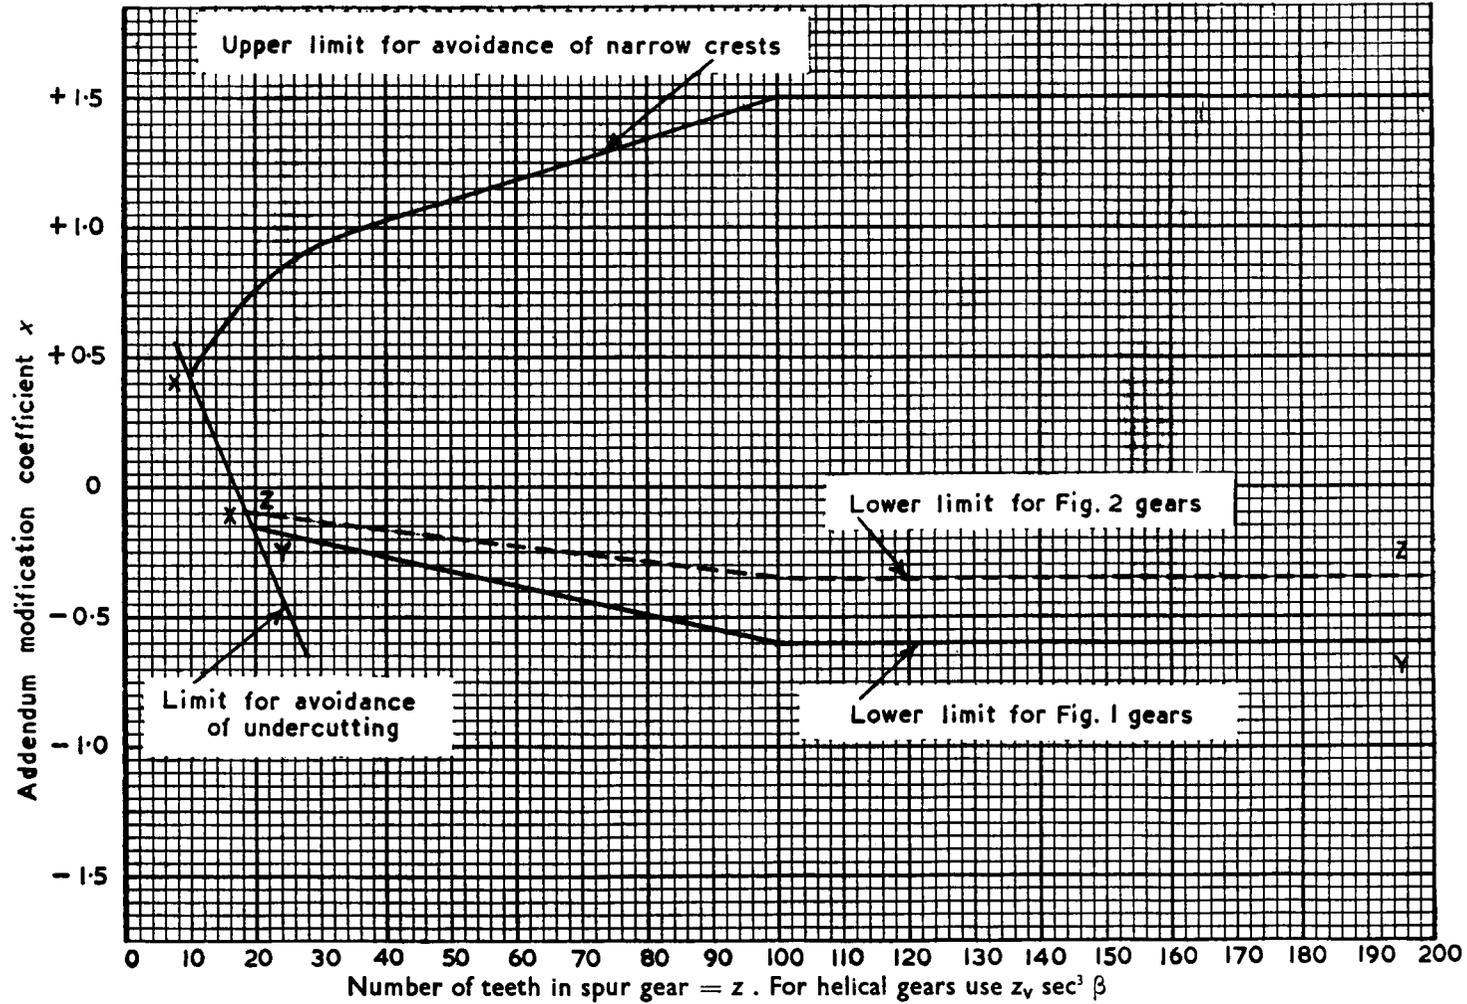

Figure 3 — Limiting values of addendum modification coefficient

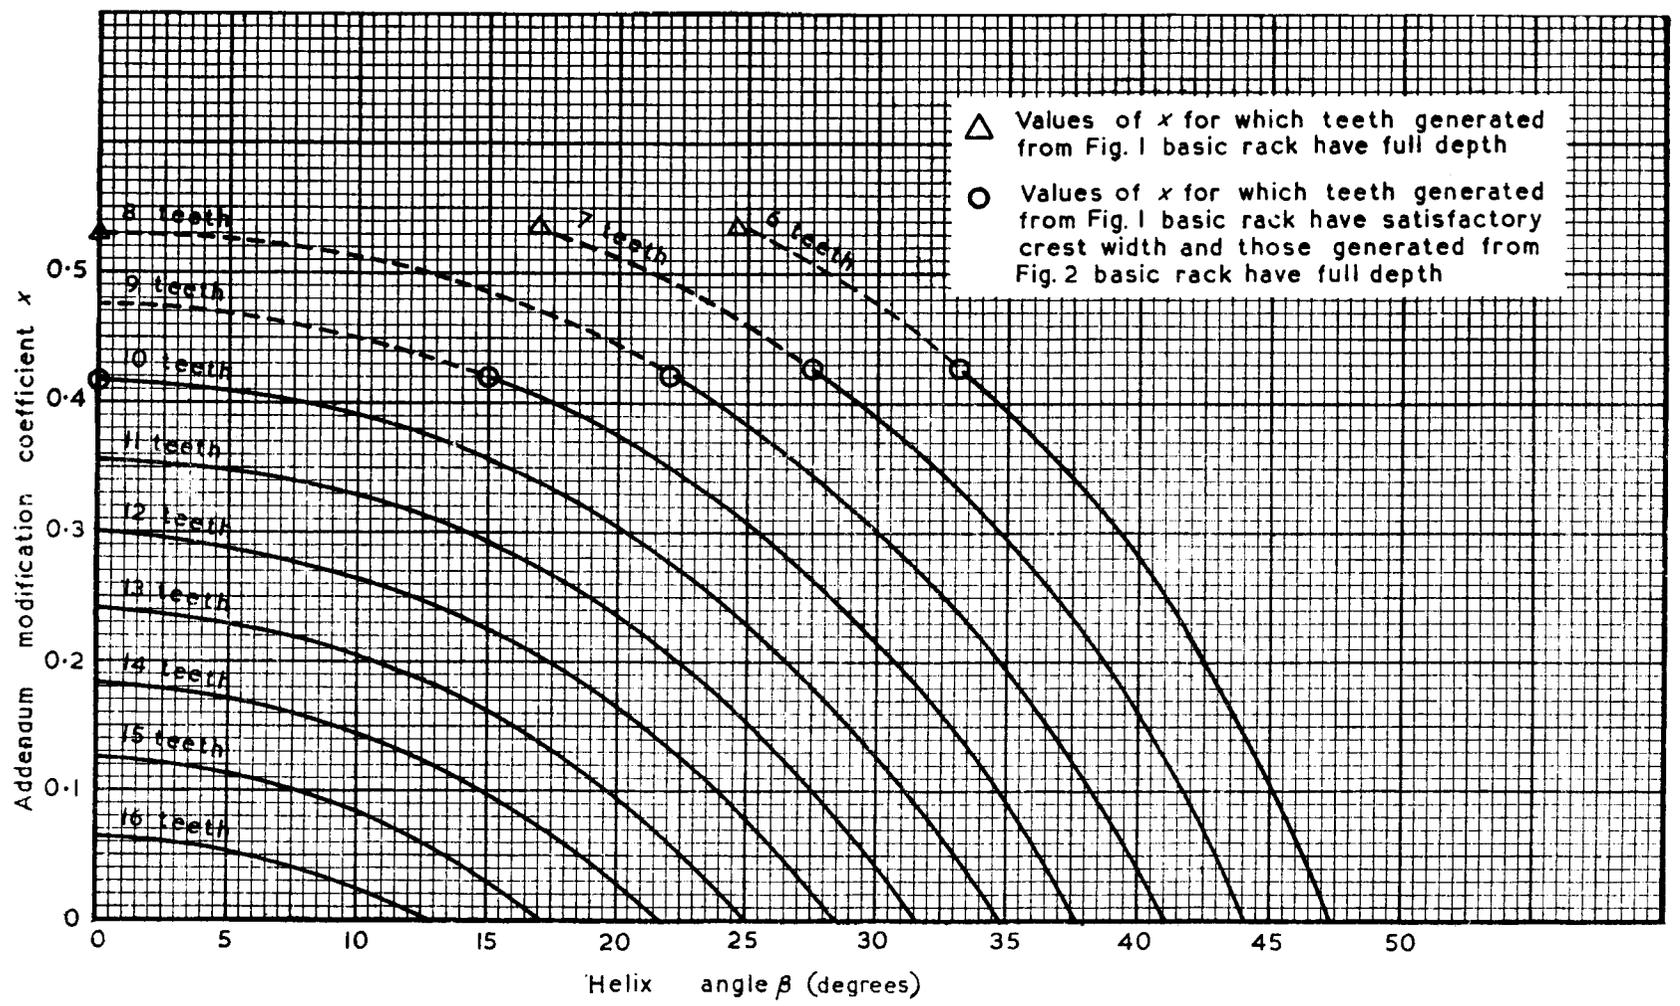

Figure 4 — Minimum permissible addendum modification coefficient for helical pinions ($\alpha_n = 20^\circ$)

Table 3 — Centre distances for spur gear pairs of unit diametral pitch for the conditions given in clause 2.2.4

3 Accuracy of gear blanks and gears

3.1 General

The measurement of individual elemental errors in fine pitch gears is sometimes difficult and often involves the use of equipment which may not readily be available. Furthermore, the individual limits of tolerance may be so very minute as to render them unrealistic as inspection criteria.

The acceptance criteria of this British Standard are therefore based on dual flank composite error testing, by which product gears are rotated in close mesh with master gears of known error, and the results given in terms of the measured variations in centre distance appropriate to the combination of master gear and product gear.

It is necessary, however, to appreciate that the variation in centre distance so measured, may include the combined effects of profile, tooth thickness, adjacent pitch and tooth alignment errors but will not necessarily be the sum of such errors. Under some circumstances, therefore, it may be necessary to control and assess elemental errors and, for this reason, coupled with the need to provide an adequate basis for accurate manufacture of the related hobs and cutters, the limits of tolerance for each possible contributing source of error are also given.

Therefore, the test methods embraced within this British Standard are:

- a. limits of tolerance on gear blanks (when applicable)
- b. dual flank composite testing
- c. assessment of elemental errors
- d. combinations of b and c.

However, recognizing the development of the single flank composite testing procedure, tolerances are given in Appendix D.

Additionally, pin dimensions for taking measurements over pins in respect of spur gears, are given in Appendix E. It should be appreciated, however, that owing to radial run-out errors, the tooth thickness measured over pins will not necessarily equate with tooth thickness at the reference circle.

The actual testing procedures to be adopted shall be the subject of agreement between purchaser and manufacturer and requirements shall be stated clearly on drawings (see Section 5 and Figure 6) and on purchase orders and contracts.

IMPORTANT NOTE. Generally, a pair of mating gears are of identical accuracy grade but, by agreement between purchaser and manufacturer, finer or coarser grades may be adopted for the pinion or wheel, or for certain elements of a pinion or wheel.

3.2 Dual flank composite testing — test pressures and limits of tolerance

The product gear shall be rotated in close mesh with a calibrated master gear under just sufficient force to ensure adequate contact whilst permitting free rotation. Forces appropriate to the pitch suitable for brass and steel product gears are given in Table 4. The errors thus revealed shall not exceed the appropriate limits of tolerance as prescribed in Table 5.

Table 4 — Forces appropriate to the pitch suitable for brass and steel product gears

	24 to 80 P_n	over 80 to 160 P_n	over 160 P_n
Master worm	8 ozf	4 ozf	2 ozf
Master wheel	16 ozf	8 ozf	4 ozf
NOTE These values may need to be reduced when checking product gears in soft materials such as plastics or aluminium.			

Table 5 — Limits of tolerance

	Class A	Class B	Class C	Class D	
	in	in	in	in	
Max. tooth to tooth composite error tolerance	10 to 19 teeth 20 to 29 teeth over 30 teeth	0.0004 0.0003 0.0002	0.0007 0.0006 0.0005	0.0010 0.0009 0.0009	0.0025 0.0023 0.0023
Max. total composite error tolerance	0.0006	0.0010	0.0016	0.0040	
Max. departure from the centre distance appropriate to this combination of master gear and product gear when meshed with a theoretically correct master gear	– 0.0003 – 0.0011	– 0.0005 – 0.0019	– 0.0005 – 0.0027	– 0.0005 – 0.0060	
Applicable to a pitch range of ^a	24 to 200 P_n	24 to 160 P_n	24 to 80 P_n	24 to 40 P_n	

NOTE Where for any reason it is desired to use a tooth thickness which is not that given for the Figure 1 basic rack, the centre distance tolerance zones given above apply.

^a Finer pitches are permissible provided that the contact ratio of the gear pair is not less than 1.1.

3.3 Limits of tolerance on blanks and gear elements

3.3.1 Gear blanks. Limits and tolerances on gear blanks shall be in accordance with Table 6. Where a topping hob or cutter is used the limits on blank diameter may not apply.

Table 6 — Limits of tolerance on gear blanks

Item	Class A	Class B	Class C	Class D
Blank diameter when used for location	h7 of BS 1916 ^a	h7 of BS 1916 ^a	h8 of BS 1916 ^a	h9 of BS 1916 ^a
Radial runout of periphery (or reference surface) relative to datum when used for setting or measurement of teeth (FIM ^b)	in 0.000 2	in 0.000 2	in 0.000 3	in 0.000 1 d_a + 0.001
Axial runout at reference diameter (FIM ^b)				
Flatness of end faces				

^a BS 1916, "Limits and fits for engineering".
^b Full indicated movement.

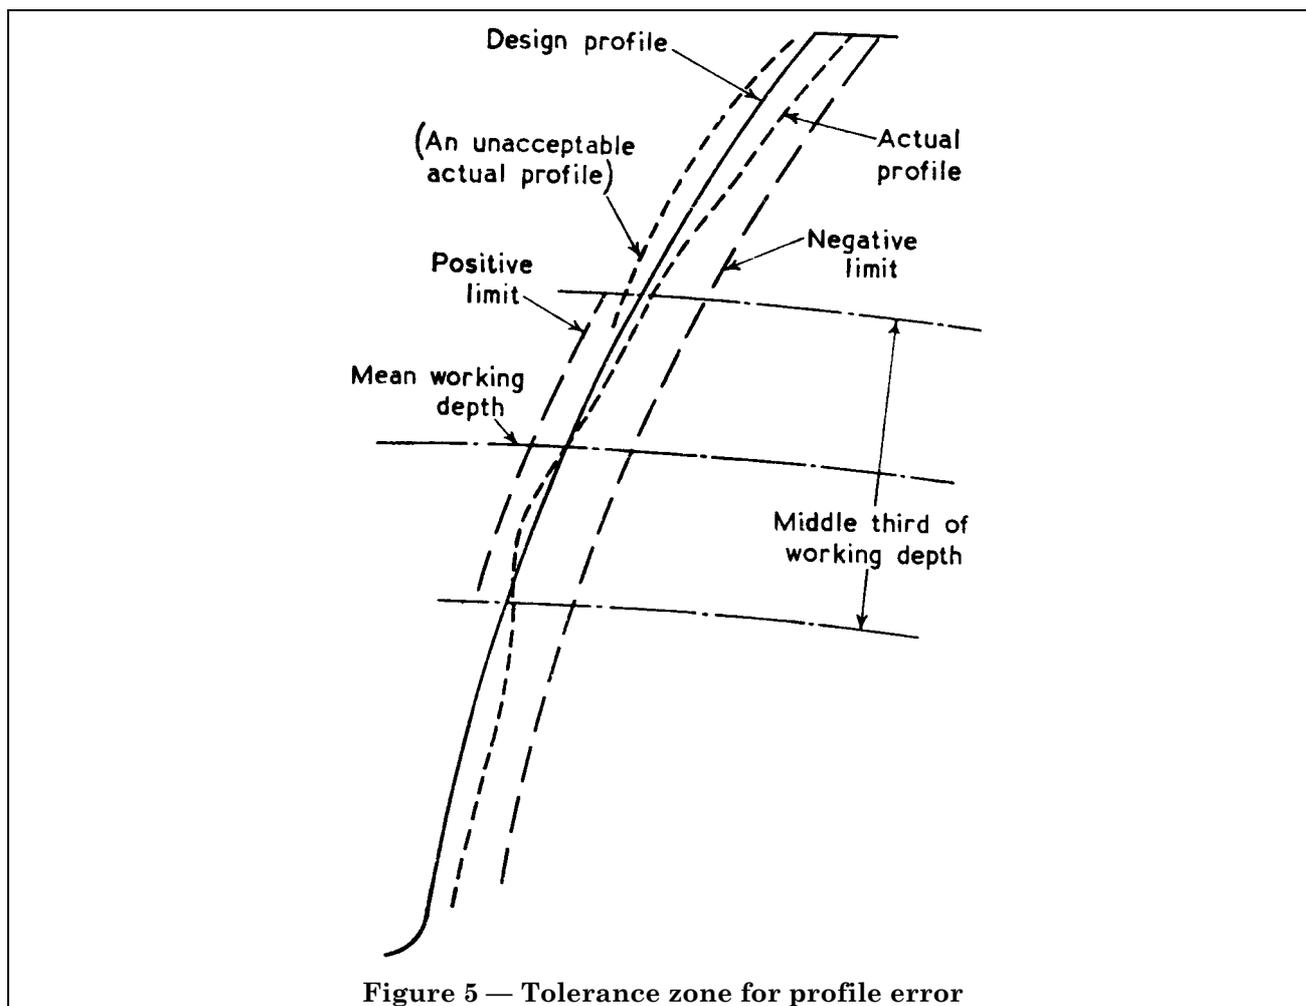

Figure 5 — Tolerance zone for profile error

3.3.2 Profile. Limits of tolerance on tooth profile are given in Table 7. The limits given are in relation to the design profile that coincides with the actual profile at mid working depth (see Figure 5).

Table 7 — Limits of tolerance on tooth profile

Class	Limits of tolerance		Generally applicable to a pitch range of
	Middle third of working depth	Outside middle third of working depth	
A	in + 0.000 05 – 0.000 10	in 0 – 0.000 1	24 to 200 inc.
B	+ 0.000 05 – 0.000 20	0 – 0.000 2	24 to 160 inc.
C	+ 0.000 10 – 0.000 30	0 – 0.000 3	24 to 80 inc.
D	+ 0.000 10 – 0.000 70	0 – 0.000 7	24 to 40 inc.

3.3.3 Pitch. Limits of tolerance on pitch (adjacent and cumulative) are given in Table 8.

Table 8 — Limits of tolerance on pitch

Class	Limits of tolerance	Generally applicable to a pitch range of
A	in $0.000\ 2\ \sqrt{l} + 0.000\ 1$	24 to 200 inc.
B	$0.000\ 32\ \sqrt{l} + 0.000\ 16$	24 to 160 inc.
C	$0.000\ 5\ \sqrt{l} + 0.000\ 25$	24 to 80 inc.
D	$0.000\ 8\ \sqrt{l} + 0.000\ 4$	24 to 40 inc.

where l = any selected length of arc, including an arc length of one pitch, but not greater than $\frac{\pi d}{2}$.

NOTE Limits of pitch tolerance are given with reference to the axis of rotation.

3.3.4 Tooth alignment. The tolerances are listed in Table 9.

Table 9 — Limits of tolerance on tooth alignment

Face width		Class A	Class B	Class C	Class D
Over	up to and inc.				
in	in	in	in	in	in
0.5	0.5	0.000 16	0.000 25	0.000 4	0.000 6
1	1	0.000 2	0.000 32	0.000 5	0.000 8
1	2	0.000 25	0.000 4	0.000 6	0.001 0
2	4	0.000 32	0.000 5	0.000 8	0.001 3

3.3.5 Radial run-out of teeth. Tolerances are given in Table 10.

Table 10 — Limits of tolerance on radial run-out of teeth

Pitch range generally applicable	Class A		Class B		Class C	Class D
	24 to 100 P_n inc.	over 100 to 200 P_n inc.	24 to 100 P_n inc.	over 100 to 160 P_n inc.	24 to 80 P_n inc.	24 to 40 P_n inc.
Tolerance	in 0.000 3	in 0.000 2	in 0.000 4	in 0.000 3	in 0.000 6	in 0.001 6
NOTE Where backlash is allowable the limit for radial run-out does not apply provided the pitch tolerances are within the limits specified in 3.3.3.						

3.3.6 Tooth thickness. Limits of tolerance for tooth thickness are given in Table 11.

Table 11 — Limits of tolerance on tooth thickness

Class	Limits of tolerance		Generally applicable to a pitch range of
	Figure 1 gears	Figure 2 gears	
A	- 0.000 3 - 0.000 6	± 0.000 25	24 to 200 inc.
B	- 0.000 6 - 0.001 0	± 0.000 4	24 to 160 inc.
C	- 0.000 9 - 0.001 6	± 0.000 8	24 to 80 inc.
D	- 0.001 6 - 0.003 0	± 0.001 6	24 to 40 inc.
NOTE 1 The above tolerances should be related to those of Table 5 when the dual flank method of composite testing is employed.			
NOTE 2 Measuring pin diameters for external and internal spur gears are given in Appendix E.			

4 Limits and tolerances of assembly

4.1 Centre distance

Limits of tolerance for centre distance of mounting shall be as given in Table 12.

Table 12 — Limits of tolerance on centre distance of mounting

Class	Limits of tolerance	Generally applicable to a pitch range of
A	in $\pm (0.000\ 08\sqrt{a} + 0.000\ 08)$	in 24 to 200 inc.
B	$\pm (0.000\ 16\sqrt{a} + 0.000\ 16)$	24 to 160 inc.
C	$\pm (0.000\ 32\sqrt{a} + 0.000\ 32)$	24 to 80 inc.
D	$\pm (0.000\ 6\sqrt{a} + 0.000\ 6)$	24 to 40 inc.
where a is the centre distance in inches.		

4.2 Depth of engagement

It may be found necessary, in the finer pitches of gears, to resort to graded inspection and selective assembly in order to maintain a satisfactory minimum depth of engagement and a suitable contact ratio.

Table 13 and Table 14 give recommended minimum values for working depth, based on contact ratios not less than 1.0 where the teeth have rounded tips or approximately 1.2 where the rounding is absent.

The larger of the two values obtained from the tables should be taken.

These data are applicable to spur gears. They will be applicable to helical or crossed helical gears if the number of teeth in each gear is multiplied by $\sec^3 \beta$.

It should be noted that backlash is increased when the working depth is less than nominal, and in circumstances in which backlash has to be limited, tolerances affecting depth of engagement are governed by consideration of the backlash rather than by contact ratio.

Table 13 — Minimum depth of engagement for spur gear pairs with 28 to 33 teeth ($z_2 + z_1$)

No. of teeth in pinion (z_1)	Minimum depth of engagement	Sum of number of teeth ($z_2 + z_1$)	Minimum depth of engagement
10–12	$1.85/P_n$	28–29	$1.80/P_n$
13–14	$1.80/P_n$	30–32	$1.75/P_n$
15–16	$1.70/P_n$	33	$1.7/P_n$

Table 14 — Minimum depth of engagement for spur gear pairs with more than 33 teeth ($z_2 + z_1$)

No. of teeth in pinion (z_1)	Minimum depth of engagement	Sum of number of teeth ($z_2 + z_1$)	Minimum depth of engagement
8	$1.8/P_n$	34–59	$1.70/P_n$
9	$1.75/P_n$	40–49	$1.65/P_n$
10–11	$1.70/P_n$	50 and above	$1.60/P_n$
12–16	$1.65/P_n$		
17 and above	$1.60/P_n$		

5 Information to be given on drawings

In accordance with the requirements of BS 308⁴⁾ the following is recommended as a standard form showing essential information required on drawings for workshops and office reference (see Figure 6 which is for illustration purposes only).

All manufacturing dimensions should be shown in the body of the drawing except those relating to gear cutting which should be shown in a table, either at the right hand side or bottom of the drawing.

The following information should be given in the table:

- Type of gear
- Number of teeth
- Normal diametral pitch
- Basic rack tooth form
- Class of gear
- Reference circle diameter
- Whole depth of tooth
- Tooth thickness on reference circle
- Hand
- Lead

⁴⁾ BS 308, "Engineering drawing practice".

Helix angle at reference cylinder

Centre distance with mating gear (optional)

Drawing No. of mating gear (optional).

A table concerning inspection data and auxiliary information may also be included. When inserting information in this table care must be exercised to avoid conflict between requirements for accuracy of individual elements and dual flank testing requirements.

Appendix A Centre distance and addendum modification

A.1 Introduction

The centre distance of a pair of gears may have any value within certain limits since two gears generated by similar tools with equal base pitch will mesh correctly. The working pressure angle, the pitch diameters and the backlash will vary with change in centre distance.

By taking advantage of these features in the design and manufacture of involute gears, the pitches listed in Table 1 will be adequate for most purposes. Gear diameters and centre distances may be varied by the choice of a suitable value for the addendum coefficients x_1 and x_2 within the upper and lower limits laid down by Figure 3.

The case where there is no addendum modification is dealt with in 2.1. In other cases the rules given apply to gears generated from the Figure 1 basic rack tooth shape. They apply substantially to the Figure 2 basic rack tooth shape also except where reference is made to close mesh and minimum backlash.

The chart given in Figure 3 has been prepared with the following points in mind:

1) *Upper limits of addendum modification coefficient.*

Too large a value will lead to an undesirably narrow crest width which should be not less than $0.3/P_n$.

If small wheels and pinions with excessively enlarged addenda are meshed together, the contact ratio becomes too low.

2) *Lower limits of addendum modification coefficient.*

Where x has a smaller value than the following the gears become undercut by generation:

$$\text{For Figure 1 type gears } x = 1.14 - \frac{z \sin^2 \alpha_t}{2 \cos \beta}$$

$$\text{Figure 2 type gears } x = 1.066 - \frac{z \sin^2 \alpha_t}{2 \cos \beta}$$

The root fillets of gears extend a minimum distance from the root circle when x is slightly greater than + 1. As x varies from this value the root fillets extend progressively further up the teeth. A limiting negative value of x is reached when the root fillets are just clear of the path of contact during engagement.

A.2 Addendum modification coefficient x_1 and x_2

A.2.1 Gears at predetermined centre distance

When the centre distance is predetermined the addendum modification coefficient x_1 and x_2 may have any value permitted by Figure 3 provided that x_1 is within the limits imposed by equations (30) and (31).

Nominal tip diameters and tooth thicknesses are then obtained from:

$$d_{a1} = d_1 + \frac{2(1 + x_1)}{P_n} \quad (15)$$

$$d_{a2} = d_2 + \frac{2(1 + x_2)}{P_n} \quad (16)$$

$$\text{Figure 1 type gears, } s_1 = \frac{1.5708 + 0.7279x_1}{P_n} \quad (17)$$

$$s_2 = \frac{1.5708 + 0.7279x_2}{P_n} \quad (18)$$

$$\text{Figure 2 type gears, } s_1 = \frac{1.4136 + 0.7279x_1}{P_n} \quad (19)$$

$$s_2 = \frac{1.4136 + 0.7279x_2}{P_n} \quad (20)$$

If the centre distance modification coefficient is equal to the sum of the addendum modification coefficients of pinion and wheel then:

$$y = x_1 + x_2 = \left(a - \frac{d_1 + d_2}{2} \right) P_n \quad (21)$$

and y has a positive or negative value other than zero;

Figure 1 type external gears have backlash at nominal dimensions

Figure 1 type internal gears have interference at nominal dimensions

Figure 1 type crossed helical gears have zero backlash at nominal dimensions.

The normal backlash (or interference) obtained is given by

$$j_n = j^* \left(\frac{y}{aP_n} \right)^2 a \quad (22)$$

where j^* is obtained from Figure 7.

For helical gears the normal backlash is obtained by using a_v in place of a in formula (22) and Figure 7, where

$$a_v = a / \cos^2 \beta \quad (23)$$

NOTE For internal gears the values of a , z_2 and d_2 are to be regarded as negative, and x_2 as negative when its sense is to enlarge the wheel. All formulae are then applicable.

If it is desired to reduce (or increase) backlash it will be necessary to increase (or decrease) tooth thickness by a secondary addendum modification Δx_1 for the pinion and Δx_2 for the wheel.

$$\frac{\Delta x_1 + \Delta x_2}{P_n} = \frac{\text{desired reduction in normal backlash}}{0.6840} \quad (24)$$

Δx_1 and Δx_2 are then added to the initial values of x_1 and x_2 obtained by equations (21), (30), (31) and used in equations (15) – (20).

In following this procedure it is necessary, if $x_1 + x_2$ have values toward the upper limits of Figure 3, to examine the root clearance and if insufficient, to modify the outside diameter of one or both gears by amounts;

$$\frac{2 \Delta x_1}{P_n} \text{ and } \frac{2 \Delta x_2}{P_n}$$

A.2.2 Gears having zero backlash requirement

Calculation of values of $x_1 + x_2$ (or a) for gears (other than crossed helical gears) which require zero backlash at nominal dimensions.

Given a , to find $(x_1 + x_2)$.

$$\cos \alpha_{tw} = \frac{(d_1 + d_2) \cos \alpha_t}{2a} \quad (25)$$

$$(x_1 + x_2) = \frac{(\text{inv} \alpha_{tw} - \text{inv} \alpha_t) (z_1 + z_2)}{2 \tan \alpha} \quad (26)$$

$$\text{where } \tan \alpha_t = \frac{\tan \alpha}{\cos \beta} \quad (27)$$

Given $(x_1 + x_2)$, to find a .

$$\text{inv}\alpha_{tw} = \text{inv}\alpha_t + \frac{2 \tan\alpha(x_1 + x_2)}{z_1 + z_2} \quad (28)$$

$$a = \frac{(d_1 + d_2) \cos\alpha_t}{2 \cos\alpha_{tw}} \quad (29)$$

NOTE $\text{inv}\alpha_t$ and $\text{inv}\alpha_{tw}$ may be obtained from tables of involute functions. An involute function of an angle is the small difference between the tangent of the angle and the value of the angle in radians.

A.3 Limiting values of x_1 and x_2

Where x_1 and x_2 have been fixed by the foregoing formulae, x_1 should lie between the following values:

$$\text{Minimum } x_1 = \frac{z_1}{z_2 + z_1} (x_1 + x_2) \quad (30)$$

$$\text{Maximum } x_1 = \frac{z_1}{z_2 + z_1} (x_1 + x_2) + 0.4 \quad (31)$$

In general, most favourable action is obtained when a high value of x_1 is used with the pinion driving the wheel and a low value of x_1 with the wheel driving the pinion.

Where a negative value of the sum $(x_1 + x_2)$ arises the value of x_2 may be below the relevant line, XX or YY, of Figure 3 provided that the sum of minimum values of $(x_1 + x_2)$ allowed by the graph is more negative than the sum required.

Appendix B Examples of calculations

Example 1. External spur gears at predetermined centre distance which differs from half the sum of the reference circles and a normal amount of backlash is permissible.

<i>Given</i>	<i>Required</i>
$z_2 = 63$	x_1 and x_2
$z_1 = 20$	d_{a2} and d_{a1}
$P_n = 24$	
$a = 1.8$ in	
Pinion driving	
Figure 1 gears.	

$$\text{From formula (21), } x_1 + x_2 = (1.8 \times 24) - \frac{(63 + 20)}{2}$$

$$= 1.7$$

$$\text{From formula (30), } x_1 \text{ min.} = \frac{20}{83} \times 1.7$$

$$= 0.41$$

$$\text{From formula (31), } x_1 \text{ max.} = \frac{20}{83} \times 1.7 + 0.4$$

$$= 0.81$$

From Figure 3, x_1 must not exceed 0.75. Selecting this value of 0.75 for x_1 then $x_2 = 1.7 - 0.75$

$$= 0.95$$

$$\text{From formula (16), } d_{a2} = \frac{63}{24} + \frac{2(1 + 0.95)}{24}$$

$$= 2.788 \text{ inches}$$

$$\text{From formula (15), } d_{a1} = \frac{20}{24} + \frac{2(1 + 0.75)}{24}$$

$$= 0.979 \text{ inch}$$

$$\text{Ans: } d_{a1} = 0.979 \quad d_{a2} = 2.788 \quad x_1 = 0.75 \quad x_2 = 0.95$$

Example 2. External spur gears at predetermined centre distance and minimum backlash.

Given

Required

$$P_n = 36$$

$$z_1, z_2, x_1, x_2$$

$$\alpha = 2.55$$

$$s_1 \text{ and } s_2$$

Ratio = 4 : 1

Pinion driving

Figure 1 gears.

Two different solutions, A and B, are given. A is derived by involute functions and B by the method of Figure 7.

Solution A. By examination, tooth numbers which give a near approach to the required centre distance are 36 and 144. With these tooth numbers and unmodified gears the centre distance would be:

$$\frac{z_1 + z_2}{2P_n} = \frac{36 + 144}{2 \times 36} = 2.5 \text{ inches}$$

$$\text{From (25) } \cos \alpha_w = \frac{2.5}{2.55} \times 0.93969 = 0.921265$$

$$\text{Whence } \alpha_w = 22.89^\circ \text{ and } \text{inv} \alpha_w = 0.02270 \quad \text{inv} \alpha = 0.014904 \text{ and } 0.022700 - 0.014904 = 0.007796$$

$$\text{From (26) } x_1 + x_2 = \frac{0.007796 \times 180}{2 \times 0.36397} = 1.928$$

$$\text{From (30) } x_1 (\text{min.}) = \frac{36}{180} \times 1.928 = 0.3856$$

$$\text{From (31) } (x_1 \text{ max.}) = \frac{36}{180} \times 1.928 + 0.4 = 0.7856, \text{ say } 0.78$$

As the pinion is driving the maximum value of x_1 may be taken and from Figure 3, x_1 can be 0.78.

$$\text{Therefore } x_2 = 1.928 - 0.78 = 1.148$$

From (17 and 18)

$$s_1 = \frac{1.5708 + 0.7279(0.78)}{36} = 0.0594 \text{ inch}$$

$$s_2 = \frac{1.5708 + 0.7279(1.148)}{36} = 0.0668 \text{ inch}$$

Note that s_2 cannot be gauged at the reference diameter, but can be used for calculation of diameter over gauge pins.

$$\text{Ans. } z_1 = 36, z_2 = 144, x_1 = 0.78, x_2 = 1.148, s_1 = 0.0594 \text{ in, } s_2 = 0.0668 \text{ inch.}$$

Solution B. Taking alternative tooth numbers, $z_1 = 37$ and $z_2 = 148$, the centre distance of unmodified

$$\text{gears would be: } \frac{z_1 + z_2}{2P_n} = \frac{185}{72} = 2.56945 \text{ inches}$$

From (21) $x_1 + x_2 = (2.55 - 2.569\ 45) / 36 = -0.700$

From A.3, this value may be used without restriction,

whence from (31), $x_{\max} = \frac{37}{185}(-0.7) + 0.4 = 0.26$ and $x_2 = -0.700 - 0.260 = -0.960$.

To check the amount of backlash obtained, using Figure 7

$$\frac{y}{P_n} = \frac{-0.700}{36} = -0.019\ 45$$

$$\frac{y}{aP_n} = \frac{-0.019\ 45}{2.55} = -0.0076 \text{ whence } j^* = 2.63$$

From (22) $j_n = \frac{2.63}{2.55} (0.019\ 45^2) = 0.000\ 39$ inch.

This is an acceptably small amount and no increase in x_1 or x_2 is justified.

From (17) and (18)

$$s_1 = \frac{1.5708 + 0.7279 \times 0.26}{36} = 0.048\ 86 \text{ inch}$$

$$s_2 = \frac{1.5708 - 0.7279 \times 0.96}{36} = 0.024\ 22 \text{ inch}$$

Note that the reference circle is near the tip of the wheel and it will not be practicable to gauge s_2 , except by gauge pin measurement.

Ans. $z_1 = 37$, $z_2 = 148$, $x_1 = 0.26$, $x_2 = -0.96$, $s_1 = 0.048\ 86$ inch, $s_2 = 0.024\ 22$ inch.

Example 3. External spur gears with no limitations other than avoidance of undercutting and backlash. (2.2.2.)

<i>Given</i>	<i>Required</i>
$z_1 = 10$	x_1 and x_2
$z_2 = 60$	s_1 and s_2
$P_n = 36$	d_{a1} and d_{a2}
	a

Two solutions are available, A) and B):

A) From Table 2, $x_1 = 0.4151$, $x_2 = 0$,

$$s_1 = \frac{1.5708 + 0.3022}{36} = 0.052\ 03 \text{ inch}$$

$$s_2 = \frac{1.5708}{36} = 0.043\ 63 \text{ inch}$$

$$\text{From (8) } d_{a1} = \frac{10 + 2(1.4151)}{36} = 0.3564 \text{ inch}$$

$$d_{a2} = \frac{60 + 2}{36} = 1.7222 \text{ inch}$$

$$\text{From Table 3, } a = \frac{35.3987}{36} = 0.983\ 30 \text{ inch}$$

B) $x_1 = 0.4150$, $x_2 = -0.4150$

whence d_{a1} and s_1 are as obtained for solution A).

$$\text{From (12) } s_2 = \frac{1.5708 - 0.3022}{36} = 0.035\ 24 \text{ inch}$$

$$d_{a2} = \frac{60 + 2(1 - 0.4151)}{36} = 1.699\ 17 \text{ inch}$$

$$\text{From (5) } a = \frac{10 + 60}{2 \times 36} = 0.972\ 22 \text{ inch}$$

Ans. (A and B): $x_1 = 0.4150$, $s_1 = 0.0520$ inch, $d_{a1} = 0.3564$ inch.

A; $x_2 = 0$, $s_2 = 0.04363$ inch, $d_{a1} = 1.7222$ inch, $a = 0.9833$ inch.

B; $x_2 = -0.4150$, $s_2 = 0.03524$ inch, $d_{a2} = 1.69917$ inch, $a = 0.9722$ inch.

Example 4. Helical gears at predetermined centre distance and minimum backlash.

<i>Given</i>	<i>Required</i>
$z_1 = 22$	d_{a1}
$z_2 = 67$	d_{a2}
$P_n = 40$	x_1
$\beta = 18^\circ$	x_2
$a = 1.1562$	

Pinion driving
 Figure 1 type gears.
 (Solution using involute functions)

Obtain, $\sec\beta = 1.05146$
 $\sec^3\beta = 1.162$
 $\tan\alpha = 0.36397$
 $\cos\alpha = 0.93969$

From (1) and (2) $d_1 = \frac{22 \times 1.05146}{40} = 0.5783$
 $d_2 = \frac{67 \times 1.05146}{40} = 1.7612$

From (27) $\tan\alpha_t = 0.36397 \times 1.05146 = 0.3827$
 whence $\alpha_t = 20.942^\circ$
 $\cos\alpha_t = 0.93394$
 $\text{inv}\alpha_t = 0.017196$

From (25)

$\cos\alpha_{tw} = \frac{(1.7612 + 0.5783) 0.93394}{2 \times 1.1562} = 0.94484$
 $\alpha_{tw} = 19.119^\circ$
 $\text{inv}\alpha_{tw} = 0.012963$

From (26) $x_1 + x_2 = \frac{(0.012963 - 0.017196)(67 + 22)}{2 \times 0.36397} = -0.51754$

From (30)

$x_1 (\text{min.}) = \frac{22}{22 + 67} (-0.51754) = -0.1279$
 $x_2 (\text{max.}) = -0.51754 + 0.1279 = -0.3896$

From (31)

$x_1 (\text{max.}) = -0.1279 + 0.4 = 0.2721$
 $x_2 (\text{min.}) = -0.51754 - 0.2721 = -0.78964$

To find the range of values of x_1 and x_2 which are permissible find z_{v1} and z_{v2} , i.e. from (7)

$z_{v1} = 22 \times 1.162 = 25.6$
 $z_{v2} = 67 \times 1.162 = 78$

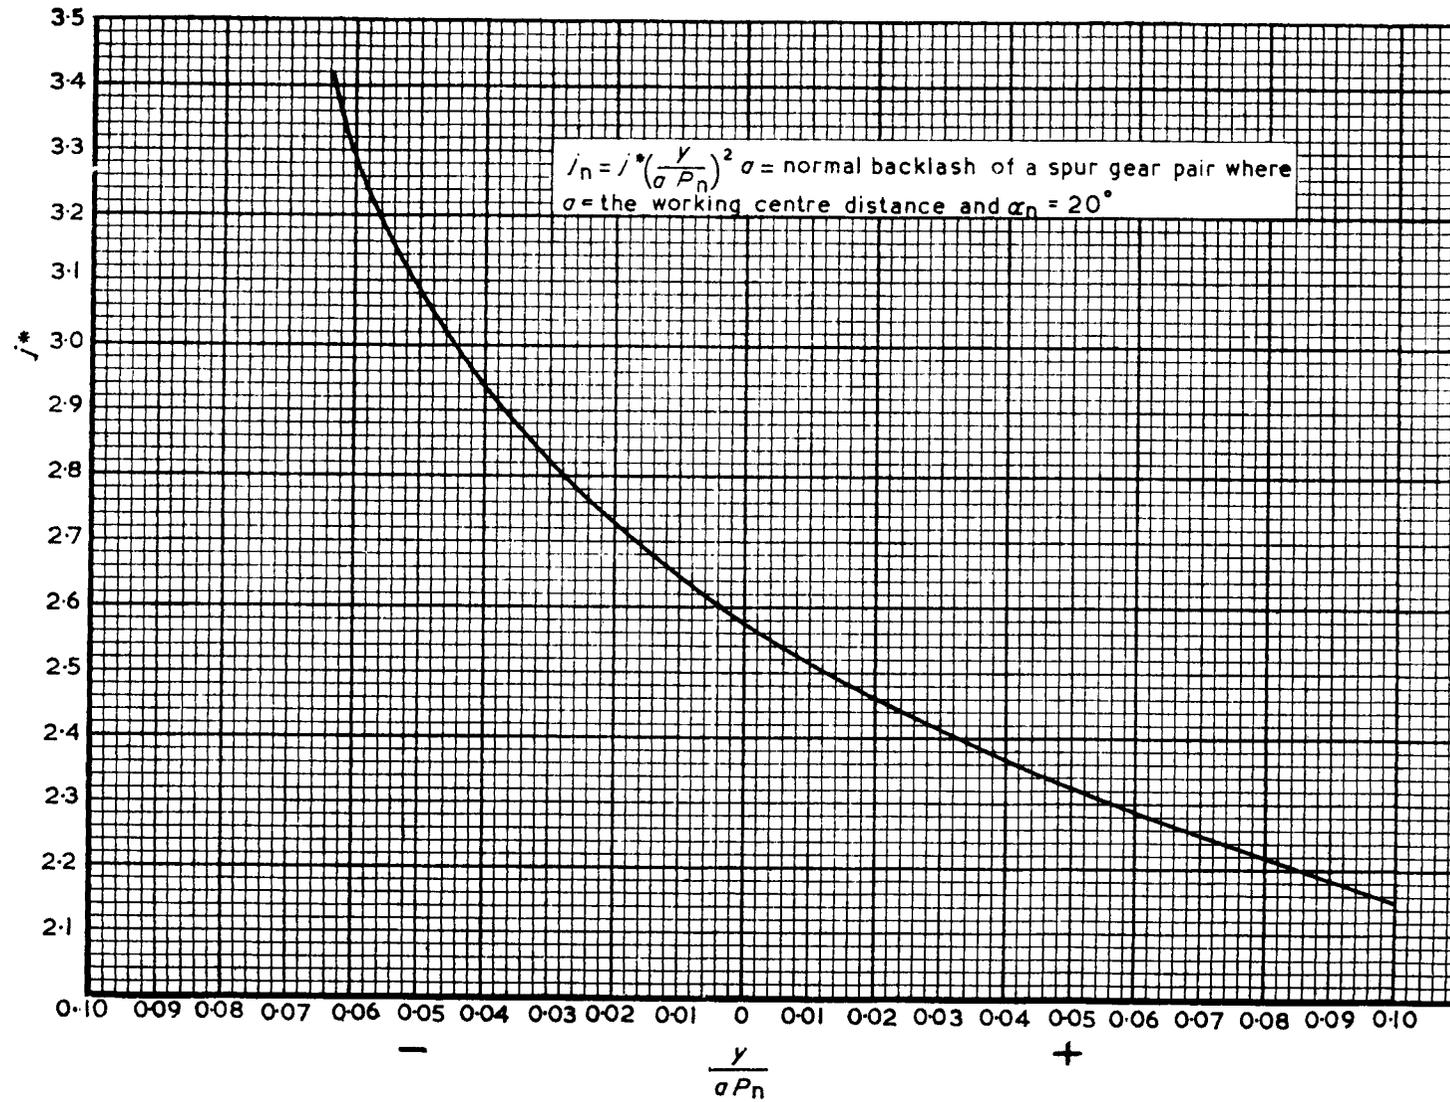

From Figure 3 we chose the value -0.48 for x_2 leaving $x_1 = -0.51754 + 0.48 = -0.0375$.

From (15) and (16)

$$d_{a1} = 0.5783 + \frac{2(1-0.0375)}{40} = 0.6264 \text{ inch}$$

$$d_{a2} = 1.7612 + \frac{2(1-0.48)}{40} = 1.7872 \text{ inch.}$$

Ans. $x_1 = -0.0375$, $x_2 = -0.48$, $d_{a1} = 0.6264$ inch, $d_{a2} = 1.7872$ inches.

Figure 7 — Chart for normal backlash when $x_1 + x_2 = y$

Appendix C Comparable diametral pitches and metric modules

Diametral pitch	Module
in	mm
24	1.058
28	0.907
32	0.794
36	0.706
40	0.635
48	0.529
64	0.397
80	0.318
100	0.254
120	0.212
140	0.181
160	0.159
180	0.141
200	0.127

Appendix D Single flank composite testing: limits of tolerance

When single flank testing is applied, the limits of tolerance are derived as follows:

- 1) *Tooth-to-tooth* composite error. For all grades, the tolerance is derived from: single pitch tolerance + tooth profile tolerance.
- 2) *Total composite error*. For all grades, the tolerance is derived from: maximum cumulative pitch tolerance + tooth profile tolerance; where the maximum cumulative pitch tolerance is derived from the value of $l = \pi d/2$.

The values derived represent errors in angular transmission when a product gear is rotated in mesh with a calibrated master gear under similar conditions to those prescribed in 3.1.

Appendix E Calculation of measuring pin dimensions for external and internal spur gears

In order to overcome the difficulty of resetting on the gear-cutting machine gears which are found to be outside dual flank tolerances in respect of size, it is necessary either to carry out dual flank testing on the machine or to adopt other methods of test at that stage of manufacture. The former method is used only in exceptional cases, whilst the practice of measurement over pins is a practical method for this purpose although insufficient in itself to dispose of the final dual flank test.

For external and internal spur gears the measuring pin diameter d_R should be calculated from the following formulae. Further information on measurement of pins is given in B.R.6001 (1) "Precision gearing for control systems and armaments"*.

For external gears of 7 to 17 teeth with positive addendum modification:

$$d_R = \frac{1.92}{P_n}$$

For external gears: $d_R = \frac{1.728}{P_n}$

For internal gears: $d_R = \frac{1.44}{P_n}$

BSI — British Standards Institution

BSI is the independent national body responsible for preparing British Standards. It presents the UK view on standards in Europe and at the international level. It is incorporated by Royal Charter.

Revisions

British Standards are updated by amendment or revision. Users of British Standards should make sure that they possess the latest amendments or editions.

It is the constant aim of BSI to improve the quality of our products and services. We would be grateful if anyone finding an inaccuracy or ambiguity while using this British Standard would inform the Secretary of the technical committee responsible, the identity of which can be found on the inside front cover. Tel: 020 8996 9000. Fax: 020 8996 7400.

BSI offers members an individual updating service called PLUS which ensures that subscribers automatically receive the latest editions of standards.

Buying standards

Orders for all BSI, international and foreign standards publications should be addressed to Customer Services. Tel: 020 8996 9001. Fax: 020 8996 7001.

In response to orders for international standards, it is BSI policy to supply the BSI implementation of those that have been published as British Standards, unless otherwise requested.

Information on standards

BSI provides a wide range of information on national, European and international standards through its Library and its Technical Help to Exporters Service. Various BSI electronic information services are also available which give details on all its products and services. Contact the Information Centre. Tel: 020 8996 7111. Fax: 020 8996 7048.

Subscribing members of BSI are kept up to date with standards developments and receive substantial discounts on the purchase price of standards. For details of these and other benefits contact Membership Administration. Tel: 020 8996 7002. Fax: 020 8996 7001.

Copyright

Copyright subsists in all BSI publications. BSI also holds the copyright, in the UK, of the publications of the international standardization bodies. Except as permitted under the Copyright, Designs and Patents Act 1988 no extract may be reproduced, stored in a retrieval system or transmitted in any form or by any means – electronic, photocopying, recording or otherwise – without prior written permission from BSI.

This does not preclude the free use, in the course of implementing the standard, of necessary details such as symbols, and size, type or grade designations. If these details are to be used for any other purpose than implementation then the prior written permission of BSI must be obtained.

If permission is granted, the terms may include royalty payments or a licensing agreement. Details and advice can be obtained from the Copyright Manager. Tel: 020 8996 7070.
